Chapter 15

Electronic Mail Security

Email Security

- email is one of the most widely used and regarded network services
- currently message contents are not secure

 may be inspected either in transit
 or by suitably privileged users on destination
 - system

Email Security Enhancements

- confidentiality
 - protection from disclosure
- authentication
 - of sender of message
- message integrity
 - protection from modification
- non-repudiation of origin
 protection from denial by sender

Pretty Good Privacy (PGP)

- widely used de facto secure email
- developed by Phil Zimmermann
- selected best available crypto algs to use
- integrated into a single program
- available on Unix, PC, Macintosh and Amiga systems
- originally free, now have commercial versions available also

PGP Operation – Authentication

- 1. sender creates a message
- 2. SHA-1 used to generate 160-bit hash code of message
- 3. hash code is encrypted with RSA using the sender's private key, and result is attached to message
- 4. receiver uses RSA or DSS with sender's public key to decrypt and recover hash code
- 5. receiver generates new hash code for message and compares with decrypted hash code, if match, message is accepted as authentic

PGP Operation – Confidentiality

- sender generates message and random 128-bit number to be used as session key for this message only
- 2. message is encrypted, using CAST-128 / IDEA/3DES with session key
- 3. session key is encrypted using RSA with recipient's public key, then attached to message
- 4. receiver uses RSA with its private key to decrypt and recover session key
- 5. session key is used to decrypt message

PGP Operation – Confidentiality & Authentication

uses both services on same message

create signature & attach to message
encrypt both message & signature
attach RSA encrypted session key

PGP Operation – Compression

- by default PGP compresses message after signing but before encrypting
 - so can store uncompressed message & signature for later verification
 - & because compression is non deterministic
- uses ZIP compression algorithm

PGP Operation – Email Compatibility

- when using PGP will have binary data to send (encrypted message etc)
- however email was designed only for text
- hence PGP must encode raw binary data into printable ASCII characters
- uses radix-64 algorithm
 - maps 3 bytes to 4 printable chars
 - also appends a CRC
- PGP also segments messages if too big

PGP Operation – Summary

(a) Generic Transmission Diagram (from A)

(b) Generic Reception Diagram (to B)

Chapter 15

PGP Session Keys

- need a session key for each message

 of varying sizes: 56-bit DES, 128-bit CAST or IDEA, 168-bit Triple-DES
- generated using ANSI X12.17 mode
- uses random inputs taken from previous uses and from keystroke timing of user

PGP Public & Private Keys

- since many public/private keys may be in use, need to identify which is actually used to encrypt session key in a message
 - could send full public-key with every message
 - but this is inefficient
- rather use a key identifier based on key
 - is least significant 64-bits of the key
 - will very likely be unique
- also use key ID in signatures

PGP Key Rings

- each PGP user has a pair of keyrings:
 - public-key ring contains all the public-keys of other PGP users known to this user, indexed by key ID
 - private-key ring contains the public/private key pair(s) for this user, indexed by key ID & encrypted keyed from a hashed passphrase

PGP Key Management

- rather than relying on certificate authorities
- in PGP every user is own CA
 - can sign keys for users they know directly
- forms a "web of trust"
 - trust keys have signed
 - can trust keys others have signed if have a chain of signatures to them
- key ring includes trust indicators
- users can also revoke their keys

S/MIME (Secure/Multipurpose Internet Mail Extensions)

- security enhancement to MIME email
 original Internet RFC822 email was text only
 - MIME provided support for varying content types and multi-part messages
 - with encoding of binary data to textual form
 - S/MIME added security enhancements
- have S/MIME support in various modern mail agents: MS Outlook, Netscape etc

S/MIME Functions

• enveloped data

– encrypted content and associated keys

- signed data
 - encoded message + signed digest
- clear-signed data
 - cleartext message + encoded signed digest
- signed & enveloped data

nesting of signed & encrypted entities

S/MIME Cryptographic Algorithms

- hash functions: SHA-1 & MD5
- digital signatures: DSS & RSA
- session key encryption: ElGamal & RSA
- message encryption: Triple-DES, RC2/40 and others
- have a procedure to decide which algorithms to use

S/MIME Certificate Processing

- S/MIME uses X.509 v3 certificates
- managed using a hybrid of a strict X.509 CA hierarchy & PGP's web of trust
- each client has a list of trusted CA's certs
- and own public/private key pairs & certs
- certificates must be signed by trusted CA's

Certificate Authorities

- have several well-known CA's
- Verisign one of most widely used
- Verisign issues several types of Digital IDs
- with increasing levels of checks & hence trust
 - Class Identity Checks Usage
 - 1 name/email check web browsing/email
 - 2+ enroll/addr check email, subs, s/w validate
 - 3+ ID documents e-banking/service access

Summary

- have considered:
 - secure email
 - PGP
 - S/MIME
